1 Introduction

Elliptic integrals are hard to solve and make little sense. Fortunately, algebraic geometry can help us. These will be my personal notes which will accumulate many resources, which I will try to reference, though I doubt I will give when each one was used. The current list is

- *Elliptic Funcations and Applications* (Lawden)
- *Elliptic Curves* (McKean, Moll)
- often wikipedia
- nlab

- *Algebraic Curves and Riemann Surfaces* (Miranda)
- *Arithmetic of Elliptic Curves* (Silverman)

These books may use different conventions, but I will keep mine uniform (unless I make an error, in which case please do let me know).

2 Preliminaries

We should hopefully not need too many preliminaries in these notes, but those that we do will form two main categories: algebraic geometry and Riemann surfaces. I desire to eventually make notes about these subjects, but in the interim this will suffice.

2.1 Complex Analysis

I will fix some notation with a definition:

Definition 2.1. Denote the *Upper Half Plane (UHP)* in \mathbb{C} as

$$H = \{z \in \mathbb{C} \mid \Im z > 0\}$$

Recall that for any distinct $z_1, z_2, z_3 \in \mathbb{C}$ we have a Mobius transform that sends them to $0, 1, \infty$ given by

$$f(z) = \frac{z - z_1}{z - z_3} \frac{z_2 - z_3}{z_2 - z_1}$$

Definition 2.2. Given distinct $z_0, z_1, z_2, z_3 \in \mathbb{C}$ the *cross ratio* is

$$\frac{z_0 - z_1}{z_0 - z_3} \frac{z_2 - z_3}{z_2 - z_1}$$

Proposition 2.3. Distinct $z_0, z_1, z_2, z_3 \in \mathbb{C}$ lie on a circline iff their cross-ratio is real.

Definition 2.4. The *modular group* is

$$\Gamma = PSL(2, \mathbb{Z}) = SL(2, \mathbb{Z}) / \{\pm I\}$$

Theorem 2.5 (Liouville). A bounded entire function $f : \mathbb{C} \rightarrow \mathbb{C}$ is constan.

2.2 Algebraic Geometry

2.3 Riemann Surfaces

2.3.1 Riemann Sphere

2.3.2 Smooth Projective Plane Curves

Definition 2.6. A \mathbb{C} -polynomial $F(\mathbf{x}) = F(x_1, \dots, x_n)$ is *homogeneous of degree d* if

$$\forall \lambda \in \mathbb{C}, F(\lambda \mathbf{x}) = \lambda^d F(\mathbf{x})$$

Definition 2.7. The *projective plane curve* defined by the homogeneous polynomial $F : \mathbb{C}^3 \rightarrow \mathbb{C}$ is the closed subset

$$X = \{[x : y : z] \in \mathbb{P}^2 \mid F(x, y, z) = 0\} \subset \mathbb{P}^2$$

Remark. Note that this is well defined as $F(x, y, z) = 0 \Leftrightarrow \lambda^d F(x, y, z) = F(\lambda x, \lambda y, \lambda z) = 0$

Definition 2.8. A homogeneous polynomial $F : \mathbb{C}^n \rightarrow \mathbb{C}$ is **singular** at x (i.e. x is a **singular point**) if $\forall 1 \leq i \leq n$

$$\left. \frac{\partial F}{\partial x_i} \right|_x = 0$$

The polynomial is said to be **non-singular** if it has no singular points

Proposition 2.9. The projective plane curve corresponding to a non-singular homogeneous polynomial is a compact Riemann surface.

2.3.3 Complex Tori

Definition 2.10. A map between Riemann surfaces $f : X \rightarrow Y$ is called an **isomorphism** iff the induced maps on open subsets of \mathbb{C} is bijective and analytic. If there is an isomorphism between X, Y , they are said to be isomorphic.

Definition 2.11. Fix $\omega_1, \omega_2 \in \mathbb{C}$ linearly independent over \mathbb{R} and let

$$L = L(\omega_1, \omega_2) = \mathbb{Z}\omega_1 \oplus \mathbb{Z}\omega_2 \subset \mathbb{C}$$

The **complex tori with lattice L** is $X = \mathbb{C}/L$. The corresponding **fundamental cell** is

$$\mathfrak{F} = \mathfrak{F}(X) = \{\alpha\omega_1 + \beta\omega_2 \mid \alpha, \beta \in [0, 1)\}$$

Proposition 2.12. Complex tori are Riemann surfaces.

Proposition 2.13. Two complex tori with lattices $L(\omega_1, \omega_2), L(\omega'_1, \omega'_2)$ are isomorphic iff \exists a fractional linear transformation sending $\frac{\omega_2}{\omega_1} \mapsto \frac{\omega'_2}{\omega'_1}$

Proposition 2.14. Every complex tori can be written with a lattice the form $L(1, \tau)$ where $\Im\tau > 0$

Remark. From the above results we can view the orbits of the modular group acting on the UHP as a list of all possible complex structures on the topological torus. We will always assume $\frac{\omega_2}{\omega_1}$ has positive imaginary part.

2.3.4 Degree of a Map

Definition 2.15. Let $f : \mathbb{C} \rightarrow \mathbb{C}$ be meromorphic at $z_0 \in \mathbb{C}$ about which it's Laurent series $\sum_n c_n(z - z_0)^n$. The **order** of f at z_0 is

$$\text{ord}_{z_0}(f) = \min \{n \mid c_n \neq 0\}$$

Remark. This definition naturally extends to maps between Riemann surfaces by taking local coordinates around the points.

Lemma 2.16. Let $f, g : X \rightarrow \mathbb{C}$ be non-zero meromorphic functions and $p \in X$. Then

- $\text{ord}_p(fg) = \text{ord}_p(f) + \text{ord}_p(g)$
- $\text{ord}_p\left(\frac{1}{f}\right) = -\text{ord}_p(f)$
- $\text{ord}_p\left(\frac{f}{g}\right) = \text{ord}_p(f) - \text{ord}_p(g)$

Proof. The first result follows from multiplying together the Laurent series. The second and third then follow. \square

Lemma 2.17. Let X be a Riemann surface and $f : X \rightarrow \mathbb{C}$ a non-constant meromorphic function. The set

$$\{p \in X, \text{ord}_p(f) \neq 0\} \subset X$$

is discrete.

Proof. If the set of poles of f had an accumulation point, around this point f would have no Laurent series. A similar argument gives no accumulation point for zeros. \square

Corollary 2.18. Let X be a compact Riemann surface and $f : X \rightarrow \mathbb{C}$ a non-constant meromorphic function. The set

$$\{p \in X, \text{ord}_p(f) \neq 0\} \subset X$$

is finite.

Definition 2.19. Let $F : X \rightarrow Y$ be a map between Riemann surfaces holomorphic at $p \in X$. The **multiplicity** of F at p is $\text{mult}_p(F) = m$ the unique integer s.t. in local coordinates around p F is represented by

$$h(z) = h(z_0) + \sum_{i \geq m} c_i (z - z_0)^i$$

Definition 2.20. Let $F : X \rightarrow Y$ be a non-constant holomorphic map of Riemann surfaces. $p \in X$ is called a **ramification point** if $\text{mult}_p(F) \geq 2$. $y \in Y$ is called a **branch point** if $y = F(p)$ for some ramification point p .

Remark. The thing to note here is that, generically, $\text{mult}_p(F) = 1$

Proposition 2.21. Let $f : X \rightarrow \mathbb{C}$ be a meromorphic function and $F : X \rightarrow \mathbb{C}_\infty$ the associated holomorphic map. Then

1. If $p \in X$ is a zero of f , $\text{mult}_p(F) = \text{ord}_p(f)$
2. If $p \in X$ is a pole of f , $\text{mult}_p(F) = -\text{ord}_p(f)$
3. If $p \in X$ is neither a zero or a pole, $\text{mult}_p(F) = \text{ord}_p(f - f(p))$

Proposition 2.22. Let $F : X \rightarrow Y$ be a holomorphic non-constant map of Riemann surfaces and consider the map $d.(F) : Y \rightarrow \mathbb{Z}$

$$d_y(F) = \sum_{p \in F^{-1}(y)} \text{mult}_p(F)$$

The map d is constant.

Definition 2.23. Let $F : X \rightarrow Y$ be a holomorphic non-constant map of Riemann surfaces. The **degree** of F is

$$\deg(F) = d_y(F) \text{ for some } y \in Y$$

Proposition 2.24. Let X be a compact Riemann surface and $f : X \rightarrow \mathbb{C}$ a non-constant meromorphic function. Then

$$\sum_{p \in X} \text{ord}_p(f) = 0$$

Proof. Consider the corresponding map $F : X \rightarrow \mathbb{C}_\infty$. Let $\{x_i\} = F^{-1}(0)$, $\{y_j\} = F^{-1}(\infty)$. Then

$$\begin{aligned} \sum_p \text{ord}_p(f) &= \sum_i \text{ord}_{x_i}(f) + \sum_j \text{ord}_{y_j}(f) \\ &= \sum_i \text{mult}_{x_i}(F) - \sum_j \text{mult}_{y_j}(F) \\ &= d_0(F) - d_\infty(F) = 0 \end{aligned}$$

□

Remark. As f can only have finitely many poles and zeros, for all but finitely many $p \in X$ we have $\text{ord}_p(f) = 0$ so the sum makes sense.

Theorem 2.25 (Hurwitz Formula). Let $F : X \rightarrow Y$ be a non-constant holomorphic map between compact Riemann surfaces. Then

$$g(X) - 1 = \deg(F) [g(Y) - 1] + \frac{1}{2} \sum_{p \in X} [\text{mult}_p(F) - 1]$$

where g is the genus of the underlying topological surface.

Part I Functions

3 Periodic Functions

We will start with some general results about periodic complex functions. We fix $f : \mathbb{C} \rightarrow \mathbb{C}$ to be a non-constant meromorphic single valued function.

Lemma 3.1. *The periods of f form a \mathbb{Z} -module L*

Proposition 3.2. *L is either*

- *trivial, ($= 0$)*
- *rank 1, ($= \omega\mathbb{Z}$)*
- *rank 2, ($= \omega_1\mathbb{Z} \oplus \omega_2\mathbb{Z}$)*

Definition 3.3. *A function with rank-2 L is called an **elliptic function** and L is called the **period lattice**.*

Definition 3.4. *Given a period lattice L , a choice of ω_1, ω_2 s.t. $L = \omega_1\mathbb{Z} \oplus \omega_2\mathbb{Z}$ is called a **primitive pair**. For a primitive pair we call $\tau = \frac{\omega_2}{\omega_1}$ the **period ratio**.*

It is common, as we will do now, to restrict the period ratio to have real imaginary part

Proposition 3.5. *Any pairs of primitive pairs are related by a fractional linear transform $\in SL(2, \mathbb{R})$. The corresponding period ratios are related by a map in the modular group*

Definition 3.6. *An **elliptic function field** is the class $K = K(X)$ of functions of rational character on the complex torus X*

Remark. *Identifying X with \mathbb{C}/L is equivalent to identifying $K(X)$ with double periodic functions on the universal cover of X , \mathbb{C} .*

Proposition 3.7. *$K(X)$ is a differential field with differential $\frac{d}{dz}$ inherited from the coordinate z on the universal cover.*

Proposition 3.8. *$\deg f = 0$ iff f is constant*

Proof. $\deg(f) = 0$ iff f has no poles. Pulling back to a doubly periodic function on \mathbb{C} , it is a bounded entire function, so constant by Liouville's theorem. \square

Lemma 3.9. *Let $f \in K(X)$. Then*

$$\oint_{\partial \mathfrak{F}(X)} f(z) dz = 0$$

Proof. Use periodicity of the function. \square

Remark. *This can be used to show $\sum_{p \in X} \text{ord}_p(f) = 0$ for X a complex torus, by considering the integral of $\frac{1}{2\pi i} \frac{f'}{f} \in K(X)$*

This result has some powerful corollaries, which we will see here now:

Proposition 3.10. $\forall f \in K(X)$, $\deg f \neq 1$.

Proof. If $\deg f = 1$ then the residue at the pole is

$$\frac{1}{2\pi i} \oint_{\partial \mathfrak{F}(X)} f(z) dz = 0$$

so there is no pole. □

Proposition 3.11. Take $f \in K(X)$ and let p_1, \dots, p_d be the zeros, q_1, \dots, q_d the poles. Then

$$\sum p_i - q_i \in L$$

Proof. Let $L = L(\omega_1, \omega_2)$

$$\begin{aligned} \sum p_i - q_i &= \frac{1}{2\pi i} \oint z d(\log f(z)) \\ &= \frac{1}{2\pi i} \left\{ \int_0^{\omega_1} [z - (z + \omega_2)] d(\log f(z)) - \int_0^{\omega_2} [z - (z + \omega_1)] d(\log f(z)) \right\} \\ &= \omega_1 \underbrace{\left[\frac{1}{2\pi i} \int_0^{\omega_2} d(\log f(z)) \right]}_{\in \mathbb{Z}} - \omega_2 \underbrace{\left[\frac{1}{2\pi i} \int_0^{\omega_1} d(\log f(z)) \right]}_{\in \mathbb{Z}} \end{aligned}$$

where we know the integrals are integer values as f takes the same values at the corners, so the argument must differ by an element of $2\pi i\mathbb{Z}$ □

4 Theta Functions

4.1 Definitions

We start this section with a warning. There are *many* different ways of writing theta functions, and so you will need to be on your toes to connect those in these notes with those in other documents. These will start with the definition in

Definition 4.1. For $\tau \in \mathbb{C}$, $\text{Im}(\tau) > 0$, define the **Riemann theta function**

$$\theta(z) = \theta(z|\tau) = \sum_{n \in \mathbb{Z}} e^{\pi i [n^2 \tau + 2nz]}$$

Remark. This is the definition given in Miranda and on Wikipedia (as of June 2020).

Proposition 4.2. The series converges absolutely and uniformly on compact subset of \mathbb{C} . Hence θ is an analytic function on \mathbb{C} .

Proposition 4.3. We have

$$\begin{aligned} \theta(z+1) &= \theta(z) \\ \theta(z+\tau) &= e^{-\pi i [\tau + 2z]} \theta(z) \end{aligned}$$

Corollary 4.4. $\theta(z_0) \Leftrightarrow \forall m, n \in \mathbb{Z}, \theta(z_0 + m + n\tau) = 0$ and the order of the zero is the same

Proposition 4.5. The only zeros of θ are

$$\frac{1+\tau}{2} + L(1, \tau)$$

and all these zeros are simple.

Definition 4.6. The *translated theta function* is

$$\theta^{(x)}(z) = \theta(z - (1/2) - (\tau/2) - x)$$

Definition 4.7. The *Jacobi theta functions* are

$$\theta_1(z|\tau) =$$

5 Jacobi Elliptic Functions

Definition 5.1. The *sinus amplitudinus* function is $sn : \mathbb{C} \rightarrow \mathbb{C}$ given by

$$x = \int_0^{sn(x,k)} \frac{dy}{\sqrt{(1-y^2)(1-k^2y^2)}}$$

6 The Weierstrass \wp Function

From our discussion of doubly-periodic functions, we know the minimal degree of a non-constant function is 2, so the simplest possible cases are

- two simple poles
- one double pole

We will construct the latter case.

Definition 6.1. Pick a complex torus X with lattice L . The corresponding **Weierstrass function** is $\wp : \mathbb{C} \rightarrow \mathbb{C}$

$$\wp(z) = \wp(z|L) = \frac{1}{z^2} + \sum_{\omega \in L \setminus 0} \left[\frac{1}{(z-\omega)^2} - \frac{1}{\omega^2} \right]$$

Proposition 6.2. The infinite sum is convergent and hence the \wp function is well defined.

Proposition 6.3. \wp has the following properties:

- Even, i.e. $\wp(z) = \wp(-z)$.
- Double periodic with period lattice L
- $\deg \wp = 2$ as a map $\mathbb{C}/L \rightarrow \mathbb{P}^1$, with only one double pole at $z = 0$
- $\forall c \in \mathbb{C}^\times, \wp(cz|cL) = \wp(z|L)$
- $\wp'(z) = -2 \sum_{\omega \in L} (z - \omega)^{-3}$
- \wp' is odd

- $\forall \omega \in L, \wp'(\omega/2) = 0$ and the half periods are the only roots.
- Let ω_1, ω_2 be the primitive roots and $e_1 = \wp(\omega_1/2)$, $e_2 = \wp(\omega_1/2 + \omega_2/2)$, $e_3 = \wp(\omega_2/2)$. Then e_1, e_2, e_3 are distinct.

Proposition 6.4. \wp satisfies the differential equations

$$\begin{aligned} (\wp')^2 &= 4(\wp - e_1)(\wp - e_2)(\wp - e_3) \\ &= 4\wp^3 - g_2\wp - g_3 \end{aligned}$$

where

$$\begin{aligned} g_2 &= 60 \sum_{\omega \in L \setminus 0} \omega^{-4} \\ g_3 &= 140 \sum_{\omega \in L \setminus 0} \omega^{-6} \end{aligned}$$

Part II

Integrals

7 Elliptic integrals

7.1 Elliptic Integral of the First Kind

Let us start by stating our assumptions of this section, namely:

- $u \in \mathbb{R}$
- $k \in (0, 1)$.

We make the following definition:

Definition 7.1. *Jacobi's incomplete elliptic integral of the first kind is the map $H \rightarrow \mathbb{C}$*

$$x \mapsto \int_0^x \frac{1}{\sqrt{(1-t^2)(1-k^2t^2)}} dt$$

where the integrand is taken to be real and positive for $t \in (-1, 1)$, and at the branch points $\pm 1, \pm \frac{1}{k}$ the contour should take an infinitesimal circle above the point (i.e remaining in the UHP).

Definition 7.2. *The complete elliptic integral of the first kind is*

$$K = K(k) = \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}} \in \mathbb{R}$$

and the *complementary integral of the first kind* is

$$K' = K'(k) = \int_1^{\frac{1}{k}} \frac{dt}{\sqrt{(t^2-1)(1-k^2t^2)}} \in \mathbb{R}$$

Proposition 7.3. *We have the following results about $K(k)$:*

1. $K(-k) = K(k)$
2. $\lim_{k \rightarrow 0+} K(k) = \frac{\pi}{2}$
3. $K(ik) = \frac{1}{\sqrt{1+k^2}} K\left(\frac{k}{\sqrt{1+k^2}}\right)$

4. $K(i) = \frac{1}{4}B\left(\frac{1}{4}, \frac{1}{2}\right)$ (B the beta function)
5. $K'(k) = K(k')$ where $k' = \sqrt{1-k^2}$
6. $K(k) = (1+k_1)K(k_1)$ for $k_1 = \frac{1-k'}{1+k'}$
7. $K(k) = \frac{\pi}{2} \prod_{n=1}^{\infty} (1+k_n)$ for $k_{n+1} = \frac{1-k'_n}{1+k'_n}$
8. $K(k) = \frac{1}{1+k}K\left(\frac{2\sqrt{k}}{1+k}\right)$ (Landen's Transformation)

Proof. We will complete the proof in parts:

1. Trivial
2. say something about convergence, and then $\int_0^1 \frac{dt}{\sqrt{1-t^2}} = \frac{\pi}{2}$ is a trig integral.
3. consider the transform $t \mapsto \frac{t}{\sqrt{1+k^3(1-t^2)}}$
4. $K(i) = \int_0^1 \frac{dt}{\sqrt{1-t^4}} = \frac{1}{4} \int_0^1 t^{-\frac{3}{4}}(1-t)^{-\frac{1}{2}} dt$ making the substitution $t \mapsto t^{\frac{1}{4}}$.
5. do the calculation
6. do the calculation
7. Iterate, observe $k_{n+1} < k_n$ (one can show $k_{n+1} < k_n^2$), and argue about convergence.
8. (Legendre 1811) Using the substitution $t \mapsto \frac{(1+k')x\sqrt{1-t^2}}{1-k^2t^2}$ find $K(k_1) = \frac{1+k'}{2}K(k)$ and the use Landen's transform.

□

These definitions of the complete integral make sense for the following result:

Proposition 7.4. *The incomplete elliptic integral of the first kind has the following straight line segments for ranges:*

$$\begin{array}{ll}
[0, 1] \mapsto [0, K] & [-1, 0] \mapsto [-K, 0] \\
[1, 1/k] \mapsto [K, K + iK'] & [-1/k, 1] \mapsto [-K + iK', -K] \\
[1/k, \infty) \mapsto [K + iK', iK'] & (-\infty, -1/k] \mapsto (iK', -K + iK']
\end{array}$$

Corollary 7.5. *The image of the UHP under the elliptic integral of the first kind is the interior of the rectangle with corners $\{K, -K, K + iK', -K + iK'\}$, with the boundary of the rectangle being the image of the boundary of the UHP.*

Definition 7.6. *The incomplete elliptic integral of the second kind is the map $H \rightarrow \mathbb{C}$*

$$x \mapsto \int_0^x \sqrt{\frac{1-k^2t^2}{1-t^2}} dt$$

using the contour above branch points.

Definition 7.7. *The complete elliptic integral of the first kind is*

$$E = E(k) = \int_0^1 \sqrt{\frac{1-k^2t^2}{1-t^2}} dt \in \mathbb{R}$$

and the **complementary integral of the first kind** is

$$E' = E'(k) = \int_1^{\frac{1}{k}} \sqrt{\frac{1 - k^2 t^2}{t^2 - 1}} dt \in \mathbb{R}$$

Proposition 7.8. We have the following results about $E(k)$:

1. $E'(k) = K(k') - E(k')$
2. (Legendre 1825) $KE' + EK' - KK' = \frac{\pi}{2}$

Definition 7.9. The **incomplete elliptic integral of the third kind** is the map $H \rightarrow \mathbb{C}$

$$x \mapsto \int^x \frac{1}{(t^2 - c^2)\sqrt{(1 - t^2)(1 - k^2 t^2)}} dt$$

using the contour above branch points.

7.2 Reduction of Elliptic Integrals

Definition 7.10. If $R = R(x, y)$ is a rational function in x, y and $y^2 = Q(x)$ is a polynomial of degree $d = 3, 4$ with distinct roots then the integral

$$\int R(x, y) dx$$

is called a **general elliptic integral**.

Remark. Dealing with integrals such as the above when $d = 1, 2$ or there are repeated roots are treated in your earlier calculus classes, for example:

- $d = 1$: write $y^2 = ax + b$ and make the substitution

$$x \mapsto \frac{1}{a}(x^2 - b)$$

- $d = 2$: write $y^2 = c(x - a)(x - b)$ and make the substitution

$$x \mapsto a = \frac{1}{4}(b - a) \left(x - \frac{1}{x} \right)^2$$

Remark. Depending on how the layout of this document ends up being, I may have a the section on Jacobi elliptic functions first. In this case, one would see that the incomplete integral of the first kind corresponds to the inverse of the function sn . We could also generate integrals from the inverses of cn, dn . However from theory of elliptic functions, we know we can write the inverses of these in terms of sn^{-1} , so transforms must exists for their corresponding integrals to reduce them to "known" forms. The same idea applies to the reduction of general elliptic integrals and we will see that now.

Proposition 7.11. A general elliptic integral can be written as

$$\int [y^{-1}R_1(x) + R_2(x)] dx$$

As a results of this, because any rational integral can be solved through partial fractions, in order to study general elliptic integrals we need know only how to deal with integrals of the form

$$\int \frac{R(x)}{y} dx$$

Let us start to deal with these:

7.2.1 $d = 3$

Write

$$Q(x) = (x - e_0)(x - e_1)(x - e_2)$$

with e_0, e_1, e_2 distinct. Make the substitution

$$x \mapsto x^2 + e_0$$

sending

$$\frac{dx}{y} \mapsto \frac{2dx}{\sqrt{(x^2 + e_0 - e_1)(x^2 + e_0 - e_2)}}$$

The new Q has roots $\pm\sqrt{e_1 - e_0}, \pm\sqrt{e_2 - e_0}$, so wlog we may take $d = 4$.

7.2.2 $d = 4$

We make now start procedurally:

1. Write $Q(x) = (x - e_0)(x - e_1)(x - e_2)(x - e_3)$
2. Send e_0, \dots, e_3 to $\pm 1, \pm \frac{1}{k}$ using a fractional linear transform. This sends $Q(x) \mapsto (1 - x^2)(1 - k^2 x^2)$. This is possible if the cross ratio is

$$\frac{e_0 - e_1}{e_0 - e_3} \frac{e_2 - e_3}{e_2 - e_1} = \frac{4k}{(1 + k)^2}$$

The distinctness of the e means that the cross ratio is not $0, 1, \infty$ and so $k \neq 0, \pm 1$. **There is clearly a choice involved in k here, can it be shown that this choice does not matter, for example in simple cases?**

3. Write $R(x) = R_1(x^2) + xR_2(x^2)$ and note

$$\int \frac{xR_2(x^2)}{\sqrt{(1 - x^2)(1 - k^2 x^2)}} dx = \frac{1}{2} \int \frac{R_2(x^2)}{\sqrt{(1 - x^2)(1 - k^2 x^2)}} d(x^2)$$

Hence this term reduces to previously solved cases ($d = 2$). As such we are reduced to the case of

$$\int \frac{R(x^2)}{y} dx$$

for $y^2 = (1 - x^2)(1 - k^2 x^2)$.

4. Use the identities

$$\begin{aligned} \frac{x^2 - a}{x^2 - b} &= 1 + \frac{b - a}{x^2 - b} \\ \frac{1}{(x^2 - a)(x^2 - b)} &= (a - b)^{-1} \left(\frac{1}{x^2 - a} - \frac{1}{x^2 - b} \right) \end{aligned}$$

to reduce to the classes of integrals

$$\begin{aligned} I_n &= \int \frac{x^{2n}}{y} dx \quad (n \geq 0) \\ I'_n &= \int \frac{(x^2 - c^2)^n}{y} dx \quad (n < 0) \end{aligned}$$

for $y^2 = (1 - x^2)(1 - k^2 x^2)$.

5. Use relation

$$nI_{n-1} - n(1 + k^2)I_n + (n + 1)k^2I_{n+1} - \frac{1}{2}(1 + k^2)I_n = x^{2n}y + \text{cst}$$

to reduce I_n to I_0 and I_1 . A similar technique can be applied to reduce I'_n to I'_{-1} and $I'_0 = I_0$.

Idea. The irreducible incomplete integrals are those of the first, second, and third kind:

$$\begin{aligned} I_0 &= \int \frac{1}{\sqrt{(1-x^2)(1-k^2x^2)}} dx \\ I_0 - k^2 I_1 &= \int \sqrt{\frac{1-k^2x^2}{1-x^2}} dx \\ I'_{-1} &= \int \frac{1}{(x^2-c^2)\sqrt{(1-x^2)(1-k^2x^2)}} dx \end{aligned}$$

A lemma useful in the reduction is the following:

Proposition 7.12. Suppose the map sending $e_0, \dots, e_3 \mapsto \pm 1, \pm \frac{1}{k}$ is

$$f(z) = \frac{az+b}{cz+d}$$

Then if we make the substitution $t = \frac{ax+b}{cx+d}$ we have

$$Q(x) = \prod (x - e_i) = \frac{(1-t^2)(1-k^2t^2)}{k^2(a-ct)^4 \prod (ce_i + d)^{-1}}$$

and

$$dx = \frac{ad-bc}{(a-ct)^2} dt$$

Proof. The inverse transform is

$$x = \frac{dt-b}{a-ct}$$

so

$$\begin{aligned} x - e_i &= \frac{(dt-b) - e_i(a-ct)}{a-ct} \\ &= \frac{(ce_i+d)t - (ae_i+b)}{a-ct} \\ &= \frac{t - f(e_i)}{(a-ct)(ce_i+d)^{-1}} \end{aligned}$$

The first part then follows by taking the product and knowing that the $f(e_i)$ are the roots of $(1-x^2)(1-k^2x^2)$, and matching up the coefficient of t^4 . For the second part we directly calculate.

$$\begin{aligned} dx &= \frac{d}{a-ct}(dt) + \frac{dt-b}{(a-ct)^2}c(dt) \\ &= \frac{ad-bc}{(a-ct)^2}(dt) \end{aligned}$$

□

Corollary 7.13. We have

$$\int \frac{dx}{\sqrt{(x-e_0)(x-e_1)(x-e_2)(x-e_3)}} = \pm \frac{k(ad-bc)}{\prod \sqrt{ce_i+d}} \int \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}}$$

where the \pm fixes the correct choice of sign.

Lemma 7.14. *The map sending $-1, \frac{1}{k}, -\frac{1}{k} \mapsto 0, 1, \infty$ is*

$$z \mapsto \frac{2k}{1+k} \frac{1+z}{1+kz}$$

and the inverse is

$$z \mapsto \frac{1}{k} \frac{(1+k)z - 2k}{-(1+k)z + 2}$$

Remark. *The above map isn't normalised yet, so fix it*

Example 7.15. *Consider the integral*

$$I = \int_0^2 \frac{1}{\sqrt{(2x-x^2)(4x^2+9)}} dx$$

We start by making Q monic by pulling out the factor of 2. This gives

$$I = \frac{1}{2} \int_0^2 \frac{1}{\sqrt{(2x-x^2)(x^2+9/4)}} dx$$

As such we have $Q(x) = -x(x-2)(x-3i/2)(x+3i/2)$. We can calculate the cross ratio for sending $0 \mapsto C, 2 \mapsto 0, \frac{3i}{2} \mapsto 1, \frac{-3i}{2} \mapsto \infty$:

$$C = \frac{0-2}{0+3i/2} \frac{3i/2+3i/2}{3i/2-2} = \frac{-4}{3i/2-2} = \frac{2i}{3/4+i}$$

This corresponds to a value of $k = \frac{i}{2}$. We want to construct a map sending $0, 2, \frac{3i}{2}, -\frac{3i}{2} \mapsto 1, -1, \frac{1}{k}, -\frac{1}{k}$ so we consider

$$z \mapsto \frac{z+b}{cz+d}$$

Imposing the conditions finds $b = d = -(1+c) = -\frac{3}{4}$. We can, without changing our answer, rescale all of these to integers (namely $a = 4, b = -3, c = -1, d = -3$) to make the calculations easier. For this transform we find $ad - bc = -15$. Further

$$\begin{aligned} -0-3 &= -3 \\ -2-3 &= -5 \\ -\frac{3i}{2}-3 &= -\left(3+\frac{3i}{2}\right) \\ -\frac{-3i}{2}-3 &= -\left(3-\frac{3i}{2}\right) \end{aligned}$$

giving

$$\prod (ce_i + d)^{-\frac{1}{2}} = \frac{2}{15\sqrt{3}}$$

so after the transform

$$I = \frac{-15i}{4} \times \frac{2}{15\sqrt{3}} \int_1^{-1} \frac{dt}{\sqrt{-(1-t^2)(1-k^2t^2)}} = \frac{1}{\sqrt{3}} K\left(\frac{i}{2}\right)$$

for $k = \frac{i}{2}$. Using

$$\begin{aligned} K(ik) &= \frac{1}{\sqrt{1+k^2}} K\left(\frac{k}{\sqrt{1+k^2}}\right) \\ \Rightarrow K\left(\frac{i}{2}\right) &= \frac{2}{\sqrt{5}} K\left(\frac{1}{\sqrt{5}}\right) \end{aligned}$$

we get

$$I = \int_0^2 \frac{1}{\sqrt{(2x-x^2)(4x^2+9)}} dx = \frac{2}{\sqrt{15}} K\left(\frac{1}{\sqrt{5}}\right)$$

7.3 Connection to Elliptic Functions

Recall that when we defined the incomplete elliptic integrals,

Because of the differential equation for \wp we have the following result:

Proposition 7.16. *We have*

$$z - z_0 = \frac{1}{2} \int_{\wp(z_0)}^{\wp(z)} \frac{dt}{\sqrt{(t-e_1)(t-e_2)(t-e_3)}} \mod L$$

where the each value of the integral depends on the contour chosen.

Example 7.17. *Choosing the correct sign of the radicals, we have*

$$\begin{aligned} \omega_1 &= \int_{\infty}^{e_1} \frac{dt}{\sqrt{(t-e_1)(t-e_2)(t-e_3)}} \\ \omega_2 &= \int_{e_1}^{e_2} \frac{dt}{\sqrt{(t-e_1)(t-e_2)(t-e_3)}} \end{aligned}$$
